Description

FIELD OF THE INVENTION

5 The present invention relates to a process for the polymerization of conjugated diolefins and more particularly to a polymerization process whereby a polybutadiene having a high cis-1,4-content is produced in the presence of a catalyst system based on a rare earth metal carboxylate that exhibits high activity.

BACKGROUND OF THE INVENTION

10 The use of rare earth compounds as components of organo-metallic mixed catalyst systems for the stereospecific polymerization of 1,3-butadiene to afford a polybutadiene with a high cis-1,4-structure has been known for a long time. For example, U.S. Patent 4,260,707 discloses a catalyst that may be used for polymerizing diene monomers in solution comprises (a) a reaction mixture formed by reacting a rare earth carboxylate and an aluminum compound wherein
 15 there are three hydrocarbon residues having from 1 to 20 carbon atoms attached to the aluminum, (b) a trialkyl aluminum and/or a dialkyl aluminum hydride and (c) a Lewis acid.

An improved process for preparing conjugated diolefin polymers or copolymers having a high content of 1,4-cis-units and high chain linearity is disclosed in U.S. Patent Number 4,444,903. In this process a catalytic system prepared from (a) at least one carboxylate or alcoholate of a rare earth element, (b) a tertiary organic halide and (c) an organo
 20 metallic aluminum compound not containing halide ions of the formula: $R^aR^bAlR^c$ in which R^a and R^b are alkyl residues and R^c is hydrogen or an alkyl radical.

Another example of the use of an organometallic mixed catalyst system containing a rare earth compound for producing a conjugated diene polymer is disclosed in U.S. Patent Number 4,461,883. The process is characterized by polymerizing at least one conjugated diene with a catalyst consisting of (A) a reaction product of a Lewis base and
 25 a carboxylate of a rare earth element of the lanthanum series represented by $AlR^2R^3R^4$ wherein R^2 , R^3 , and R^4 which may be identical or different represent hydrogen or alkyl substituents, although R^2 , R^3 , and R^4 may not all be hydrogen at the same time and (C) an alkyl aluminum halide represented by AlX_nR^{5-3-n} wherein X is a halide, R^5 is an alkyl group and n has the value of 1, 1.5, 2 or 3 and (D) optionally a conjugated diene.

U.S. Patent Number 4,533,711 discloses that a polybutadiene rubber composition comprising a polybutadiene
 30 having a cis-1,4-content of at least 70 per cent, an average chain length of 110 to 450 cis-1,4-units, a molecular weight distribution of at least 5.0 and containing at least 1 per cent by weight of a component having a molecular weight of not less than 25,000,000 is produced by polymerizing 1,3-butadiene in the presence of a catalyst system containing the compounds I to III as essential ingredients; (I) a compound of a lanthanum series rare earth element; (II) a trialkyl aluminum compound; and (III) a halogenated aluminum compound represented by a general formula of AlX_nR_{3-n} where-
 35 in X is a halogen atom, R is a hydrocarbon residue and n is 1 to 3; until the degree of conversion of 1,3-butadiene reaches at least 3 per cent and then adding at least one compound selected from organo aluminum hydrides represented by a general formula of AlH_mR_{3-m} wherein R is a hydrocarbon residue and m is 1 or 2 and aromatic hydrocarbons containing active hydrogen as a modifier.

However, the foregoing catalyst systems are not without their disadvantages in that some of the catalyst systems
 40 are very difficult to dissolve in the hydrocarbon solvents which are commonly employed as the reaction solvent for polymerization of 1,3-butadiene. Moreover, the catalytic activity of some of the catalyst systems is not particularly high which is a disadvantage in industrial use.

SUMMARY OF THE INVENTION

45 It is an object of this invention to provide a process for the preparation of a high molecular polybutadiene having more than 96 per cent of the butadiene units present in the cis-1,4-structure using a catalyst system based on a rare earth compound that exhibits improved catalytic activity.

Thus, in accordance with the present invention there is provided a process for producing a high molecular weight
 50 rubbery polybutadiene having a Mooney (ML1+4 @ 100°C) of at least 20.3 and having more than 96 per cent of the butadiene units present in the cis-1,4-structure which process comprises the steps of: (A) polymerizing 1,3-butadiene in a polymerization medium comprising an inert hydrocarbon which is a solvent at least for the 1,3-butadiene and the catalyst system at a temperature of from 0°C to 120°C in the presence of a catalyst system dissolved in said polymerization medium, said catalyst system being a mixture of (1) a rare earth carboxylate represented by the formula Nd
 55 (R^1CO_2)₃ wherein Nd represents the rare earth element neodymium and R^1CO_2 represents a residue of a carboxylic acid having from 4 to 12 carbon atoms, (2) an alkyl aluminum chloride compound selected from the group consisting of compounds represented by the formulae R^2AlCl_2 , $R^2_3Al_2Cl_3$ and R^2_2AlCl wherein R^2 is a hydrocarbon residue having from 8 to 12 carbon atoms and (3) an organo aluminum compound of the formula R^3_2AlH wherein R^3 is an alkyl group

having from 2 to 6 carbon atoms, the ratio of the mols of said rare earth carboxylate to the mols of said alkyl aluminum chloride compound plus said organo aluminum compound being in the range of from 1:1.5 to 1:100, (B) continuing the polymerization thus initiated to the monomer conversion desired and (c) thereafter deactivating the polymerization and recovering the polybutadiene.

DETAILED DESCRIPTION OF THE INVENTION

Now, in accordance with the present invention it has been found that a hydrocarbon soluble catalyst system prepared by combining three essential compounds namely (1) a rare earth carboxylate, (2) an alkyl aluminum chloride compound wherein the alkyl group has from 8 to 12 carbon atoms and (3) an organo aluminum compound, is highly active in the polymerization of 1,3-butadiene affording a polybutadiene having more than 96 per cent of the butadiene units present in the cis-1,4-structure.

The rare earth carboxylates useful in the production of catalysts of this invention are represented by the formula $\text{Nd}(\text{R}^1\text{CO}_2)_3$ in which Nd represents the rare earth element neodymium and R^1 represents a hydrocarbon group having from 4 to 11 carbon atoms. The group represented by R^1CO_2 is a residue of a carboxylic acid of which suitable non-limiting examples for use in the formation of the rare earth carboxylates are pentanoic acid, 2,2-dimethyl propanoic acid (pivalic acid), hexanoic acid, cyclohexanoic acid, heptanoic acid, octanoic acid, 2-ethylhexanoic acid, 2,2-dimethyl hexanoic acid, nonanoic acid, decanoic acid and versatic acid which is variously described as being tert-decanoic acid or a mixture of branched carboxylic acids wherein R^1 has the value of 8 to 10. Preferably the group represented by R^1CO_2 in the formula $\text{Nd}(\text{R}^1\text{CO}_2)_3$ for the rare earth carboxylate is a residue of a carboxylic acid selected from the group consisting of 2,2-dimethyl propanoic acid (pivalic acid), 2-ethylhexanoic acid and versatic acid and most preferably the group represented by R^1CO_2 is a residue of versatic acid.

The alkyl aluminum chloride compound that is suitable for use in the catalyst system is selected from the group consisting of compounds represented by the formulae R^2AlCl_2 , $\text{R}^2_3\text{Al}_2\text{Cl}_3$ and R^2_2AlCl wherein R^2 is a hydrocarbon residue having from 8 to 12 carbon atoms. Groups which may be represented by R^2 are exemplified by the straight and branched chain aliphatic hydrocarbon groups such as octyl, 2-ethylhexyl, nonyl, decyl, undecyl, and dodecyl. Illustrative nonlimiting examples of suitable alkyl aluminum chloride compounds include dioctyl aluminum chloride, octyl aluminum sesquichloride, octyl aluminum dichloride, didecyl aluminum chloride, decyl aluminum sesquichloride, decyl aluminum dichloride, didodecyl aluminum chloride, dodecyl aluminum sesquichloride, and dodecyl aluminum dichloride. The preferred alkyl aluminum chloride compound for use in the catalyst system is selected from the group consisting of dioctyl aluminum chloride, octyl aluminum sesquichloride, octyl aluminum dichloride, didodecyl aluminum chloride, dodecyl aluminum sesquichloride and dodecyl aluminum dichloride; dioctyl aluminum chloride, octyl aluminum sesquichloride and octyl aluminum dichloride being preferred more, and octyl aluminum sesquichloride being the alkyl aluminum chloride compound of choice.

In the practice of the process of the present invention it has been found, that although when there is a mixture of both a sterically larger group such as an octyl group and a sterically smaller group such as an ethyl group in the alkyl aluminum chloride compound, the activity of the catalyst system is somewhat improved relative to the activity of the catalyst system wherein there is only a sterically small group such as the ethyl group present in the alkyl aluminum chloride compound, the activity is not improved as much as when there are only sterically larger groups present in the organo aluminum chloride compound.

The third component that is appropriate for use in the catalyst system is an organo aluminum compound represented by the formula R^3_2AlH wherein R^3 is an alkyl group having from 2 to 6 carbon atoms. Illustrative nonlimiting examples of such compounds include diethyl aluminum hydride, dipropyl aluminum hydride, diisopropyl aluminum hydride, dibutyl aluminum hydride, diisobutyl aluminum hydride, dipentyl aluminum hydride, and dihexyl aluminum hydride. The preferred organo aluminum compound for use in the catalyst system is selected from the group consisting of diethyl aluminum hydride, diisopropyl aluminum hydride and diisobutyl aluminum hydride, diisobutyl aluminum hydride being the compound that is the most preferred.

The ratio of the mols of the rare earth carboxylate to the mols of the alkyl aluminum chloride compound plus said organo aluminum compound is in the range of from 1:1.5 to 1:100, preferably from 1:1.5 to 1:60.

The ratio of the mols of the rare earth carboxylate to the mols of the alkyl aluminum chloride compound is preferably in the range of from 1:0.5 to 1:10, more preferably in the range of from 1:1 to 1:5.

The ratio of the mols of rare earth carboxylate to the mols of organo aluminum compound is preferably in the range of from 1:1 to 1:50, more preferably in the range of from 1:2 to 1:20.

The process of the present invention is carried out in a polymerization medium containing an inert hydrocarbon which is a solvent at least for the 1,3-butadiene and the catalyst system. Suitable inert hydrocarbons for use as the polymerization medium include aliphatic, cycloaliphatic, aromatic and monoolefinic hydrocarbons and mixtures thereof. More specifically suitable hydrocarbons are those selected from the group consisting of C_4 to C_8 aliphatic hydrocarbons, C_5 to C_{10} cyclic aliphatic hydrocarbons, C_6 to C_9 aromatic hydrocarbons, C_4 to C_6 monoolefinic hydrocarbons and

mixtures thereof. Illustrative nonlimiting examples of the aforementioned hydrocarbons include butane, pentane, hexane, heptane, cyclopentane, cyclohexane, benzene, toluene, xylene, butene-1 and pentene-1. Preferably the process of the present invention is carried out in a polymerization medium that does not contain an aromatic hydrocarbon, that is the process is carried out in hydrocarbons selected from the group consisting of C₄ to C₈ aliphatic hydrocarbons, C₅ to C₁₀ cyclic aliphatic hydrocarbons and C₄ to C₆ monoolefinic hydrocarbons and mixtures thereof as the catalyst system exhibits the improved activity in such a polymerization medium. More preferably the inert hydrocarbon for use as the polymerization medium is selected from hexane and cyclohexane.

The proportion or concentration of 1,3-butadiene in the polymerization medium can vary somewhat depending on the particular solvent or diluent medium employed. In most solvents in which both the 1,3-butadiene and the product-polymer are completely soluble, from 12 to 35 per cent by weight of the 1,3-butadiene, based on the total weight of the solution can be employed with the production of a flowable cement.

To prepare the catalyst system, solutions of components (1), (2) and (3) may be mixed in any desired sequence in a suitable inert solvent with stirring. The same solvent as that used for the polymerization of the 1,3-butadiene may be used for preparation of the catalyst system. The temperature at which preparation of the catalyst system is carried out may vary within a wide range and is generally limited by the melting point and the boiling point of the solvent used. Temperatures ranging from 0°C to 120°C are suitable. Preparation of the catalyst system may be carried out separately or, preferably, by the addition and mixing of catalyst components (2) and (3) with the polymerization reaction mixture followed by the addition of catalyst component (1). If desired, components (2) and (3) may be mixed together before they are added to the polymerization mixture. It is immaterial whether the 1,3-butadiene which is to be polymerized is added before or after the catalyst components or whether the 1,3-butadiene is added between the addition of one catalyst component and the addition of another catalyst component.

The temperature at which the process of the present invention can be carried out can vary somewhat, temperatures in the range of from about 0°C to 120°C, the lower temperature limit being dictated more by the freezing point of the reaction medium rather than by the catalyst activity. Normally the process of the present invention is conducted within a temperature range of from 40°C to 90°C.

In accordance with the process of this invention, a high molecular weight polybutadiene having more than 96 per cent of the butadiene units present in the cis-1,4-configuration is produced by polymerizing, in a reaction vessel provided with agitation, 1,3-butadiene dissolved in a polymerization medium comprising an inert hydrocarbon solvent in the presence of a catalyst system comprising (1) a rare earth carboxylate represented by the formula Nd(R¹CO₂)₃, (2) an alkyl aluminum chloride compound wherein the alkyl groups attached to the aluminum are sterically large and (3) an organo aluminum compound of the formula R³₂AlH that exhibits improved activity.

The polymerization may be carried out as a batchwise polymerization or as a continuous process polymerization, the procedure of continuous process polymerization being preferred with 1,3-butadiene and the catalyst system being continuously supplied to the reaction vessel.

Without limiting in any way the scope of the invention, the process of the present invention may consist of combining 1,3-butadiene with a mixture of inert hydrocarbons that comprise the polymerization medium. To this combination, there is then added a solution of an alkyl aluminum chloride compound and an organo aluminum compound and an organo aluminum compound. Following thorough agitation and a period of aging (if desired) the solution mixture can be conveniently introduced into one or a series of reaction vessels where the polymerization is to take place. The rare earth carboxylate may be added to the solution containing the 1,3-butadiene or directly where the polymerization is to occur. After the polymerization has reached the desired degree of conversion, the reaction mixture is treated with an agent that deactivates the catalyst, such agents being selected from water and alcohol. Catalyst residues may be removed by water washes and alcohol washes. The polymer may simultaneously be precipitated by the addition of alcohol or alcohol solvent mixtures that both destroy the catalyst and precipitate the polymer as a solid crumb which may be further washed with water or alcohol and subsequently dried by methods well known in the art.

In the examples which illustrate the practice of this invention, the analytical techniques below were employed for the analysis of the high cis-1,4-polybutadienes produced.

The weight percentages of the cis-1,4-, the trans-1,4- and the vinyl-1,2-structures in the polybutadiene products were determined by Fourier Transform InfraRed (FTIR) Spectroscopy using polymeric films cast from solution on to potassium bromide plates. The areas of the absorbance peaks at 995 cm⁻¹, 968 cm⁻¹, 912 cm⁻¹, 895 cm⁻¹ and 740 cm⁻¹ were integrated and the weight percentages of the cis-1,4, trans-1,4 and vinyl-1,2-structures were then determined from empirically derived relationships.

The Mooney viscosity of the product was determined according to ASTM method D-1646 and the dilute solution viscosity was obtained according to a modified version of ASTM method D-3616 wherein the amount of sample used in the preparation of the polymeric solution was 0.3000 ± 0.0002 grams and the flow times of the polymeric solution and the solvent were determined at a temperature of 30 ± 0.02°C.

1,3-Butadiene obtained from Union Carbide and Phillips pure grade hexane were purified by passage through a column packed with 4Å (1 Å = 0.1 nm) molecular sieves, followed by passage through a column packed with 13X

molecular sieves. A 20 weight per cent solution of diisobutyl aluminum hydride in hexane obtained from the Aldrich Chemical Company and the trialkyl aluminums obtained from Ethyl Corporation were used as received. An 18.6 weight per cent solution of neodymium versatate in hexane was prepared according to the procedure in U.S. Patent Number 5,220,045 (Knauf et al to Bayer).

The following examples are intended to illustrate specific embodiments of the invention and are not intended to limit the scope of the invention.

Example 1

This example illustrates the rate of polymerization of 1,3-butadiene using the catalyst system of the process of the present invention.

A 10 weight per cent solution of octyl aluminum sesquichloride ($\text{Oct}_3\text{Al}_2\text{Cl}_3$) in hexane was prepared by mixing octyl aluminum dichloride (6.33 g, 0.03 mol), a 25 weight per cent solution of trioctyl aluminum in heptane (14.67 g, 0.01 mol) and hexane (79 g) together under an atmosphere of argon.

Three 1 litre glass bottles each capped with a 2 hole crown cap sealed with a fluorinated rubber gasket were each charged with hexane (425.0 g), 1,3-butadiene (75.0 g, 1.39 mol) (15 per cent by weight of 1,3-butadiene based on the total weight of the 1,3-butadiene and the solvent), diisobutyl aluminum hydride (1.75 ml, 1.97 millimol) and the solution of the octyl aluminum sesquichloride (0.39 g, 0.0788 millimol) and the bottles containing the solutions placed in a water bath at a temperature of 60°C and shaken for 15 minutes in order to equilibrate the contents. To each solution there was then added a solution of the neodymium versatate (0.35 ml, 0.0825 millimol) and polymerization of the 1,3-butadiene initiated. After 15 minutes the reaction mixtures in one of the bottles was treated with a mixture of methanol and water in order to deactivate the catalyst and coagulate the polybutadiene which was then dried in an oven under vacuum at a temperature of 60°C for 24 hours. The polybutadiene was analyzed for percentage conversion, Mooney viscosity, dilute solution viscosity and microstructure and the results are given in Table I. The reaction mixtures in the remaining two bottles were treated in a similar manner at the end of 30 minutes and 60 minutes respectively and the results are given in Table I.

Example 2

A reaction using the same procedure as in Example 1 was carried out with the exception that a 1.0 molar solution of ethyl aluminum sesquichloride ($\text{Et}_3\text{Al}_2\text{Cl}_3$) (0.78 g, 0.0788 millimol) in heptane was used in place of the solution of octyl aluminum sesquichloride.

The results are given in Table I.

Example 3

A reaction using the same procedure as in Example 1 was carried out with the exception that a solution of ethyl octyl aluminum sesquichloride having the average composition ($\text{Et}_{1.5}\text{Oct}_{1.5}\text{Al}_{2.0}\text{Cl}_{3.0}$) (1.33 g, 0.0788 millimol) in hexanes was used in place of the solution of octyl aluminum sesquichloride.

The ethyl octyl aluminum sesquichloride was prepared by mixing a 1.0 molar solution of ethyl aluminum dichloride (150 ml, 0.15 mol), a 25.3 weight per cent solution of trioctyl aluminum in heptane (48.31 g, 0.03 mol) and a 1.0 molar solution of triethyl aluminum in cyclohexane (16.7 ml, 0.016 mol) together under an atmosphere of argon.

The results of the polymerizations are given in Table I.

Example 4

A reaction using the same procedure as in Example 1 was carried out with the exception that a solution of ethyl octyl aluminum sesquichloride having the average composition ($\text{Et}_{1.5}\text{Oct}_{1.5}\text{Al}_{2.0}\text{Cl}_{3.0}$) (1.43 g, 0.0788 millimol) in heptane/hexane was used in place of the solution of octyl aluminum sesquichloride.

The ethyl aluminum sesquichloride was prepared by mixing together a 1 molar solution of ethyl aluminum dichloride (60 ml, 0.06 mol) with a 25.3 weight per cent solution of trioctylaluminum (28.99 g, 0.02 mol) in heptane under an atmosphere of argon.

The results of the polymerizations are given in Table I.

On comparing the results from Examples 1 through 4 in Table I, it can be seen that when there is complete substitution of the ethyl group by the octyl group in the alkyl aluminum sesquichloride, the activity of the catalyst system is increased significantly, the percentage conversion of the 1,3-butadiene to high cis-1,4-polybutadiene after 30 minutes being comparable to the percentage conversion after 60 minutes when a portion or all of the alkyl group in the alkyl aluminum sesquichloride is the sterically small ethyl group.

* Control reaction

The following examples describe the polymerizations of 1,3-butadiene using a catalyst system comprising neodymium versatate and either dioctyl aluminum chloride, octyl aluminum sesquichloride or octyl aluminum dichloride together with diisobutyl aluminum hydride.

5 Example 5

A 1 weight per cent solution of dioctyl aluminum chloride in hexane/heptane was prepared by mixing octyl aluminum dichloride (2.11 g, 0.01 mol), a 25.3 weight per cent solution of trioctyl aluminum (14.5 g, 0.01 mol) and hexane (561 g) together under an atmosphere of argon.

10 Two 1 litre glass bottles each capped with a 2 hole crown cap sealed with a fluorinated rubber gasket was charged with hexane (425 g), 1,3-butadiene (75.0 g, 1.39 mol) (15 per cent by weight of 1,3-butadiene based on the total weight of the 1,3-butadiene and the solvent), diisobutyl aluminum hydride (1.75 ml, 1.97 millimol) and the solution of dioctyl aluminum chloride (6.8 g, 0.24 millimol) and the bottles containing the solutions placed in a water bath at a temperature of 60°C and shaken for 15 minutes in order to equilibrate the contents. To each solution there was then added a solution
15 of the neodymium versatate (0.35 ml, 0.0825 millimol) and polymerization of the 1,3-butadiene initiated. After 15 minutes the reaction in one of the bottles was treated with a mixture of methanol and water in order to deactivate the catalyst and coagulate the polybutadiene which was then dried in an oven under vacuum at a temperature of 60°C for 24 hours. The polybutadiene was analyzed for percentage conversion, Mooney viscosity, dilute solution viscosity and the results are given in Table II. The reaction mixture in the remaining bottle was treated in a similar manner at the end
20 of 60 minutes and the results are given in Table II.

Example 6

A reaction using the same procedure as in Example 5 was carried out with the exception that a 1 weight per cent solution of octyl aluminum sesquichloride was used in place of the solution of dioctyl aluminum chloride.

25 The 1 weight percent solution of octyl aluminum sesquichloride in hexane/heptane was prepared by mixing octyl aluminum dichloride (6.33 g, 0.03 mol), a 25.3 weight per cent solution of trioctyl aluminum in heptane (14.67 g, 0.01 mol) and hexane (979 g) together under an atmosphere of argon.

The results are given in Table II.

Example 7

A reaction using the same procedure as in Example 5 was carried out with the exception that a 1 weight per cent solution of octyl aluminum dichloride in hexane was used in place of the solution of dioctyl aluminum.

35 The results are given in Table II.

Example 8

40 A control reaction using the same procedure as in Example 5 was carried out with the exception that a 0.25 weight per cent solution of ethyl aluminum sesquichloride was used in place of the solution of dioctyl aluminum chloride. The results are given in Table II.

45 From the results in Table II, it can be seen that when an octyl group is substituted for the ethyl group in diethyl aluminum chloride, ethyl aluminum sesquichloride or ethyl aluminum dichloride, the activity of the catalyst system is increased, from 10 percent to 35 percent more high cis-1,4-polybutadiene being produced after 15 minutes polymerization than when the alkyl aluminum chloride compound used in the catalyst system is ethyl aluminum sesquichloride.

Claims

1. A process for the production of a high molecular weight rubbery polybutadiene having a Mooney (ML1+4 @ 100°C) of at least 20.3 and having more than 96 per cent of the butadiene units present in the cis-1,4 structure which process comprises the steps of: (A) polymerizing 1,3-butadiene in a polymerization medium comprising an inert

hydrocarbon which is a solvent at least for the 1-3-butadiene and the catalyst system at a temperature of from 0°C to 120°C in the presence of a catalyst system dissolved in said polymerization medium, said catalyst system being a mixture of (1) a rare earth carboxylate represented by the formula $\text{Nd}(\text{R}^1\text{CO}_2)_3$ wherein Nd represents the rare earth element neodymium and R^1CO_2 represents a residue of a carboxylic acid having from 4 to 12 carbon atoms, (2) an alkyl aluminum chloride compound selected from the group consisting of compounds represented by the formulae R^2AlCl_2 , $\text{R}^2_3\text{Al}_2\text{Cl}_3$ and R^2_2AlCl wherein R^2 is a hydrocarbon residue having from 8 to 12 carbon atoms and (3) an organo aluminum compound of the formula R^3_2AlH wherein R^3 is an alkyl group having from 2 to 6 carbon atoms, the ratio of the mols of said rare earth carboxylate to the mols of said alkyl aluminum chloride compound plus said organo aluminum compound being in the range of from 1:1.5 to 1:100, (B) continuing the polymerization thus initiated to the monomer conversion desired and (C) thereafter deactivating the polymerization and recovering the polybutadiene.

2. The process of Claim 1 wherein the group represented by R^1CO_2 in the neodymium carboxylate is a residue of a carboxylic acid selected from the group consisting of 2,2-diethyl propanoic acid (pivalic acid), 2-ethyl-hexanoic acid and versatic acid.
3. The process of Claim 1 wherein the alkyl aluminum chloride compound is represented by the formula $\text{R}^2_3\text{Al}_2\text{Cl}_3$ and R^2 is a hydrocarbon residue having 8 carbon atoms.
4. The process of Claim 1 wherein the alkyl aluminum chloride compound is represented by the formula R^2AlCl_2 and R^2 is a hydrocarbon residue having 8 carbon atoms.
5. The process of Claim 1 wherein the alkyl aluminum chloride compound is represented by the formula R^2_2AlCl and R^2 is a hydrocarbon residue having 8 carbon atoms.
6. The process of Claim 1 wherein the alkyl group R^3 in the organo aluminum compound of the formula R^3_2AlH has from 2 to 4 carbon atoms.
7. The process of Claim 6 wherein the alkyl group R^3 having from 2 to 4 carbon atoms is selected from the group consisting of ethyl, isopropyl and isobutyl.
8. The process of Claim 1 wherein the ratio of the mols of the rare earth carboxylate to the mols of alkyl aluminum chloride compound is in the range of from 1:0.5 to 1:10.
9. The process of Claim 1 wherein the ratio of the mols of rare earth carboxylate to the mols of organo aluminum compound is in the range of from 1:1 to 1:50.
10. The process of Claim 1 which comprises the steps of polymerizing (A) 1,3-butadiene in a polymerization medium comprising the said hydrocarbon solvent at a temperature of from 40°C to 90°C in the presence of a catalyst system dissolved in said hydrocarbon solvent, said catalyst system being (1) a rare earth carboxylate represented by the formula $\text{Nd}(\text{R}^1\text{CO}_2)_3$ wherein the group represented by R^1CO_2 is a residue of versatic acid, (2) an alkyl aluminum chloride compound represented by the formula $\text{R}^2_3\text{Al}_2\text{Cl}_3$ wherein R^2 is a hydrocarbon residue having 8 carbon atoms and (3) an organo aluminum compound of the formula R^3_2AlH wherein the alkyl group R^3 is isobutyl, the ratio of the mols of said rare earth carboxylate to the mols of said alkyl aluminum chloride compound being in the range of from 1:0.5 to 1:10 and the ratio of the mols of said rare earth carboxylate to the mols of said organo aluminum compound being in the range of from 1:1 to 1:50, (B) continuing the polymerization thus initiated to the monomer conversion desired and (C) thereafter deactivating the polymerization and recovering the polybutadiene.

Patentansprüche

1. Verfahren zur Herstellung eines hochmolekularen kautschukartigen Polybutadiens mit einer Mooney-Viskosität ($\text{ML1}+4$ bei 100°C) von wenigstens 20,3, bei dem mehr als 96% der Butadieneinheiten in der cis-1,4-Struktur vorliegen, wobei das Verfahren die Schritte umfaßt:
 (A) Polymerisieren von 1,3-Butadien in einem Polymerisationsmedium, das einen inerten Kohlenwasserstoff umfaßt, der wenigstens für das 1,3-Butadien und das Katalysatorsystem ein Lösungsmittel ist, bei einer Temperatur von 0°C bis 120°C in Gegenwart eines in dem Polymerisationsmedium gelösten Katalysatorsystems, wobei es sich bei dem Katalysatorsystem um ein Gemisch von (1) einem Seltenerdmetallcarboxylat, das durch die Formel

Nd(R¹CO₂)₃ dargestellt wird, wobei Nd das Seltenerdelement Neodym darstellt und R¹CO₂ einen Rest einer Carbonsäure mit 4 bis 12 Kohlenstoffatomen darstellt, (2) einer Alkylaluminiumchloridverbindung, die aus der Gruppe ausgewählt ist, die aus Verbindungen besteht, die durch die Formeln R²AlCl₂, R²₃Al₂Cl₃ und R²₂AlCl dargestellt werden, wobei R² ein Kohlenwasserstoffrest mit 8 bis 12 Kohlenstoffatomen ist, und (3) einer Organoaluminiumverbindung der Formel R³₂AlH, wobei R³ eine Alkylgruppe mit 2 bis 6 Kohlenstoffatomen ist, handelt, wobei das Verhältnis der Mole des Seltenerdmetallcarboxylats zu den Molen der Alkylaluminiumchloridverbindung plus der Organoaluminiumverbindung im Bereich von 1:1,5 bis 1:100 liegt, (B) Fortführen der auf diese Weise eingeleiteten Polymerisation bis zu der gewünschten Monomerumsetzung und (C) danach Desaktivieren der Polymerisation und Gewinnen des Polybutadiens.

2. Verfahren gemäß Anspruch 1, wobei die durch R¹CO₂ dargestellte Gruppe in dem Neodymcarboxylat ein Rest einer Carbonsäure ist, die aus der Gruppe ausgewählt ist, die aus 2,2-Diethylpropansäure (Pivalinsäure), 2-Ethylhexansäure und Versatinsäure besteht.

3. Verfahren gemäß Anspruch 1, wobei die Alkylaluminiumchloridverbindung durch die Formel R²₃Al₂Cl₃ dargestellt wird und R² ein Kohlenwasserstoffrest mit 8 Kohlenstoffatomen ist.

4. Verfahren gemäß Anspruch 1, wobei die Alkylaluminiumchloridverbindung durch die Formel R²AlCl₂ dargestellt wird und R² ein Kohlenwasserstoffrest mit 8 Kohlenstoffatomen ist.

5. Verfahren gemäß Anspruch 1, wobei die Alkylaluminiumchloridverbindung durch die Formel R²₂AlCl dargestellt wird und R² ein Kohlenwasserstoffrest mit 8 Kohlenstoffatomen ist.

6. Verfahren gemäß Anspruch 1, wobei die Alkylgruppe R³ in der Organoaluminiumverbindung der Formel R³₂AlH 2 bis 4 Kohlenstoffatome umfaßt.

7. Verfahren gemäß Anspruch 6, wobei die Alkylgruppe R³ mit den 2 bis 4 Kohlenstoffatomen aus der Gruppe ausgewählt ist, die aus Ethyl, Isopropyl und Isobutyl besteht.

8. Verfahren gemäß Anspruch 1, wobei das Verhältnis der Mole des Seltenerdmetallcarboxylats zu den Molen der Alkylaluminiumchloridverbindung im Bereich von 1:0,5 bis 1:10 liegt.

9. Verfahren gemäß Anspruch 1, wobei das Verhältnis der Mole des Seltenerdmetallcarboxylats zu den Molen der Organoaluminiumverbindung im Bereich von 1:1 bis 1:50 liegt.

10. Verfahren gemäß Anspruch 1, das die Schritte umfaßt: (A) Polymerisieren von 1,3-Butadien in einem Polymerisationsmedium, das das Kohlenwasserstoff-Lösungsmittel umfaßt, bei einer Temperatur von 40°C bis 90°C in Gegenwart eines in dem Kohlenwasserstoff-Lösungsmittel gelösten Katalysatorsystems, wobei es sich bei dem Katalysatorsystem um (1) ein Seltenerdmetallcarboxylat, das durch die Formel Nd(R¹CO₂)₃ dargestellt wird, wobei die durch R¹CO₂ dargestellte Gruppe ein Rest von Versatinsäure ist, (2) eine Alkylaluminiumchloridverbindung, die durch die Formel R²₃Al₂Cl₃ dargestellt wird, wobei R² ein Kohlenwasserstoffrest mit 8 Kohlenstoffatomen ist, und (3) eine Organoaluminiumverbindung der Formel R³₂AlH, wobei es sich bei der Alkylgruppe R³ um Isobutyl handelt, handelt, wobei das Verhältnis der Mole des Seltenerdmetallcarboxylats zu den Molen der Alkylaluminiumchloridverbindung im Bereich von 1:0,5 bis 1:10 liegt und das Verhältnis der Mole des Seltenerdmetallcarboxylats zu den Molen der Organoaluminiumverbindung im Bereich von 1:1 bis 1:50 liegt, (B) Fortführen der auf diese Weise eingeleiteten Polymerisation bis zu der gewünschten Monomerumsetzung und (C) danach Desaktivieren der Polymerisation und Gewinnen des Polybutadiens.

Revendications

1. Procédé pour la production d'un polybutadiène caoutchouteux de haut poids moléculaire ayant une viscosité Mooney (ML1+4 à 100°C) d'au moins 20,3 et comprenant plus de 96 % des motifs butadiène présents sous forme de la structure cis-1,4, procédé qui comprend les étapes consistant :

(A) à polymériser du 1,3-butadiène dans un milieu de polymérisation comprenant un hydrocarbure inerte qui est un solvant au moins pour le 1,3-butadiène et la formulation de catalyseur, à une température de 0°C à 120°C en présence d'une formulation de catalyseur dissoute dans ledit milieu de polymérisation, ladite formulation de catalyseur consistant en un mélange (1) d'un carboxylate de terre rare représenté par la formule Nd(R¹CO₂)₃ dans

laquelle Nd représente l'élément faisant partie des terres rares consistant en néodyme et R^1CO_2 représente un résidu d'un acide carboxylique ayant 4 à 12 atomes de carbone, (2) d'un chlorure d'alkylaluminium choisi dans le groupe consistant en composés représentés par les formules R^2AlCl_2 , $R^2_3Al_2Cl_3$ et R^2_2AlCl dans lesquelles R^2 représente un résidu hydrocarboné ayant 8 à 12 atomes de carbone, et (3) d'un composé organique d'aluminium de formule R^3_2AlH dans laquelle R^3 représente un groupe alkyle ayant 2 à 6 atomes de carbone, le rapport du nombre de moles dudit carboxylate de terre rare au nombre de moles dudit chlorure d'alkylaluminium plus ledit composé organique d'aluminium étant compris dans l'intervalle de 1:1,5 à 1:100, (B) à continuer la polymérisation ainsi déclenchée jusqu'à la conversion de monomère désirée, et (C) à désactiver ensuite la polymérisation et à recueillir le polybutadiène.

2. Procédé suivant la revendication 1, dans lequel le groupe représenté par R^1CO_2 dans le carboxylate de néodyme est un résidu d'un acide carboxylique choisi dans le groupe consistant en l'acide 2,2-diéthylpropanoïque (acide pivalique), l'acide 2-éthylhexanoïque et l'acide versatique.
3. Procédé suivant la revendication 1, dans lequel le chlorure d'alkylaluminium est représenté par la formule $R^2_3Al_2Cl_3$ et R^2 représente un résidu hydrocarboné ayant 8 atomes de carbone.
4. Procédé suivant la revendication 1, dans lequel le chlorure d'alkylaluminium est représenté par la formule R^2AlCl_2 et R^2 représente un résidu hydrocarboné ayant 8 atomes de carbone.
5. Procédé suivant la revendication 1, dans lequel le chlorure d'alkylaluminium est représenté par la formule R^2_2AlCl et R^2 représente un résidu hydrocarboné ayant 8 atomes de carbone.
6. Procédé suivant la revendication 1, dans lequel le groupe alkyle R^3 dans le composé organique d'aluminium de formule R^3_2AlH a 2 à 4 atomes de carbone.
7. Procédé suivant la revendication 6, dans lequel le groupe alkyle R^3 ayant 2 à 4 atomes de carbone est choisi entre les groupes éthyle, isopropyle et isobutyle.
8. Procédé suivant la revendication 1, dans lequel le rapport du nombre de moles du carboxylate de terre rare au nombre de moles de chlorure d'alkylaluminium est compris dans l'intervalle de 1:0,5 à 1:10.
9. Procédé suivant la revendication 1, dans lequel le rapport du nombre de moles du carboxylate de terre rare au nombre de moles du composé organique d'aluminium est compris dans l'intervalle de 1:1 à 1:50.
10. Procédé suivant la revendication 1, qui comprend les étapes consistant (A) à polymériser du 1,3-butadiène dans un milieu de polymérisation comprenant le solvant hydrocarboné à une température de 40°C à 90°C en présence d'une formulation de catalyseur dissoute dans ledit solvant hydrocarboné, ladite formulation de catalyseur étant (1) un carboxylate de terre rare représenté par la formule $Nd(R^1CO_2)_3$ dans laquelle le groupe représenté par R^1CO_2 est un résidu d'un acide versatique, (2) un chlorure d'alkylaluminium représenté par la formule $R^2_3Al_2Cl_3$ dans laquelle R^2 représente un résidu hydrocarboné ayant 8 atomes de carbone, et (3) un composé organique d'aluminium de formule R^3_2AlH dans laquelle le groupe alkyle R^3 est un groupe isobutyle, le rapport du nombre de moles dudit carboxylate de terre rare au nombre de moles dudit chlorure d'alkylaluminium étant compris dans l'intervalle de 1:0,5 à 1:10 et le rapport du nombre de moles dudit carboxylate de terre rare au nombre de moles dudit composé organique d'aluminium étant compris dans l'intervalle de 1:1 à 1:50, (B) à continuer la polymérisation ainsi commencée jusqu'à la conversion de monomère désirée, et (C) à désactiver ensuite la polymérisation et à recueillir le polybutadiène.
